I have read that it is a matter of preference, but what is the difference in performance and other aspects? I'm interested in the code itself, not the memory/runtime differences. A: The only real benefit I can think of is that you have an instance of your class on the stack, which is useful for debugging. Other than that, there isn't really any difference. I'd go with whatever you think is most readable. A: The only benefit I can see is in debugging. Creating an instance of your class instead of calling the constructor creates a local reference to your object on the stack. Q: Python - Printing Out This Byte If I take this number 0xfd And convert it to a string it would be displayed as a Unicode representation (UTF-8). But what is the Python representation of the number? How would I display it as a Hexadecimal number. A: You can use the int function to convert a Unicode string to the int representation of the string: >>> unicode_str = '\u1234' >>> int(unicode_str, 16) 26496 You can use bin(num) to convert a number to a binary representation. To get a hexadecimal representation you would then need to do something like >>> bin(int(unicode_str, 16))[2:] '01' Events & Information Blues Blast the Flyers The Blues hit the 4bc0debe42
